

VacQ-Project Evolution

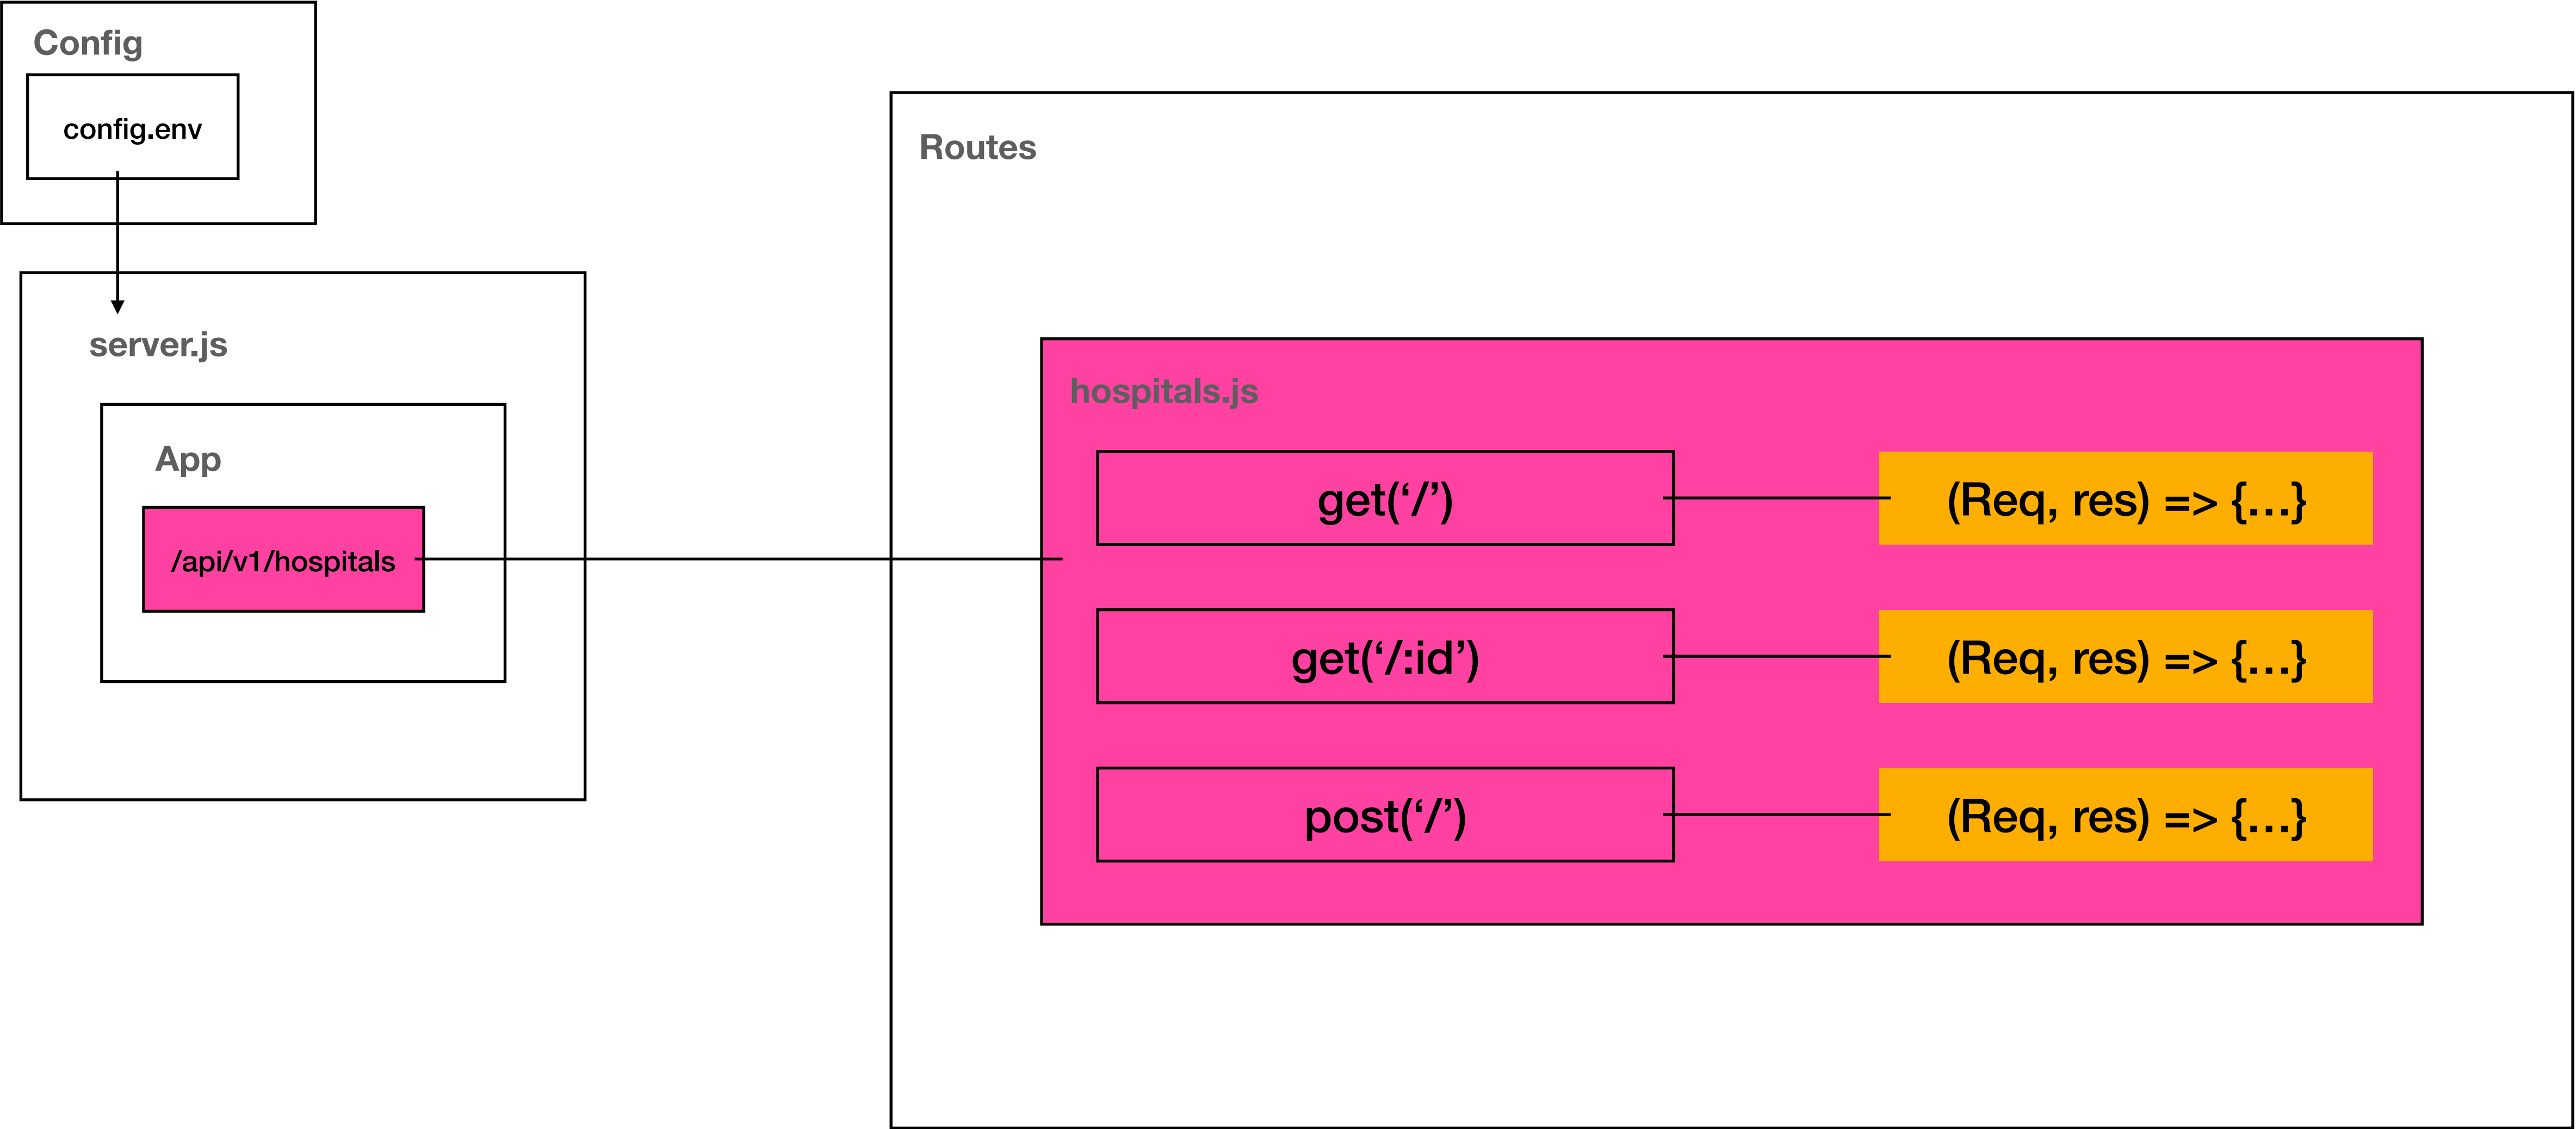

Bird's eye view : Stop the headache

noWarm

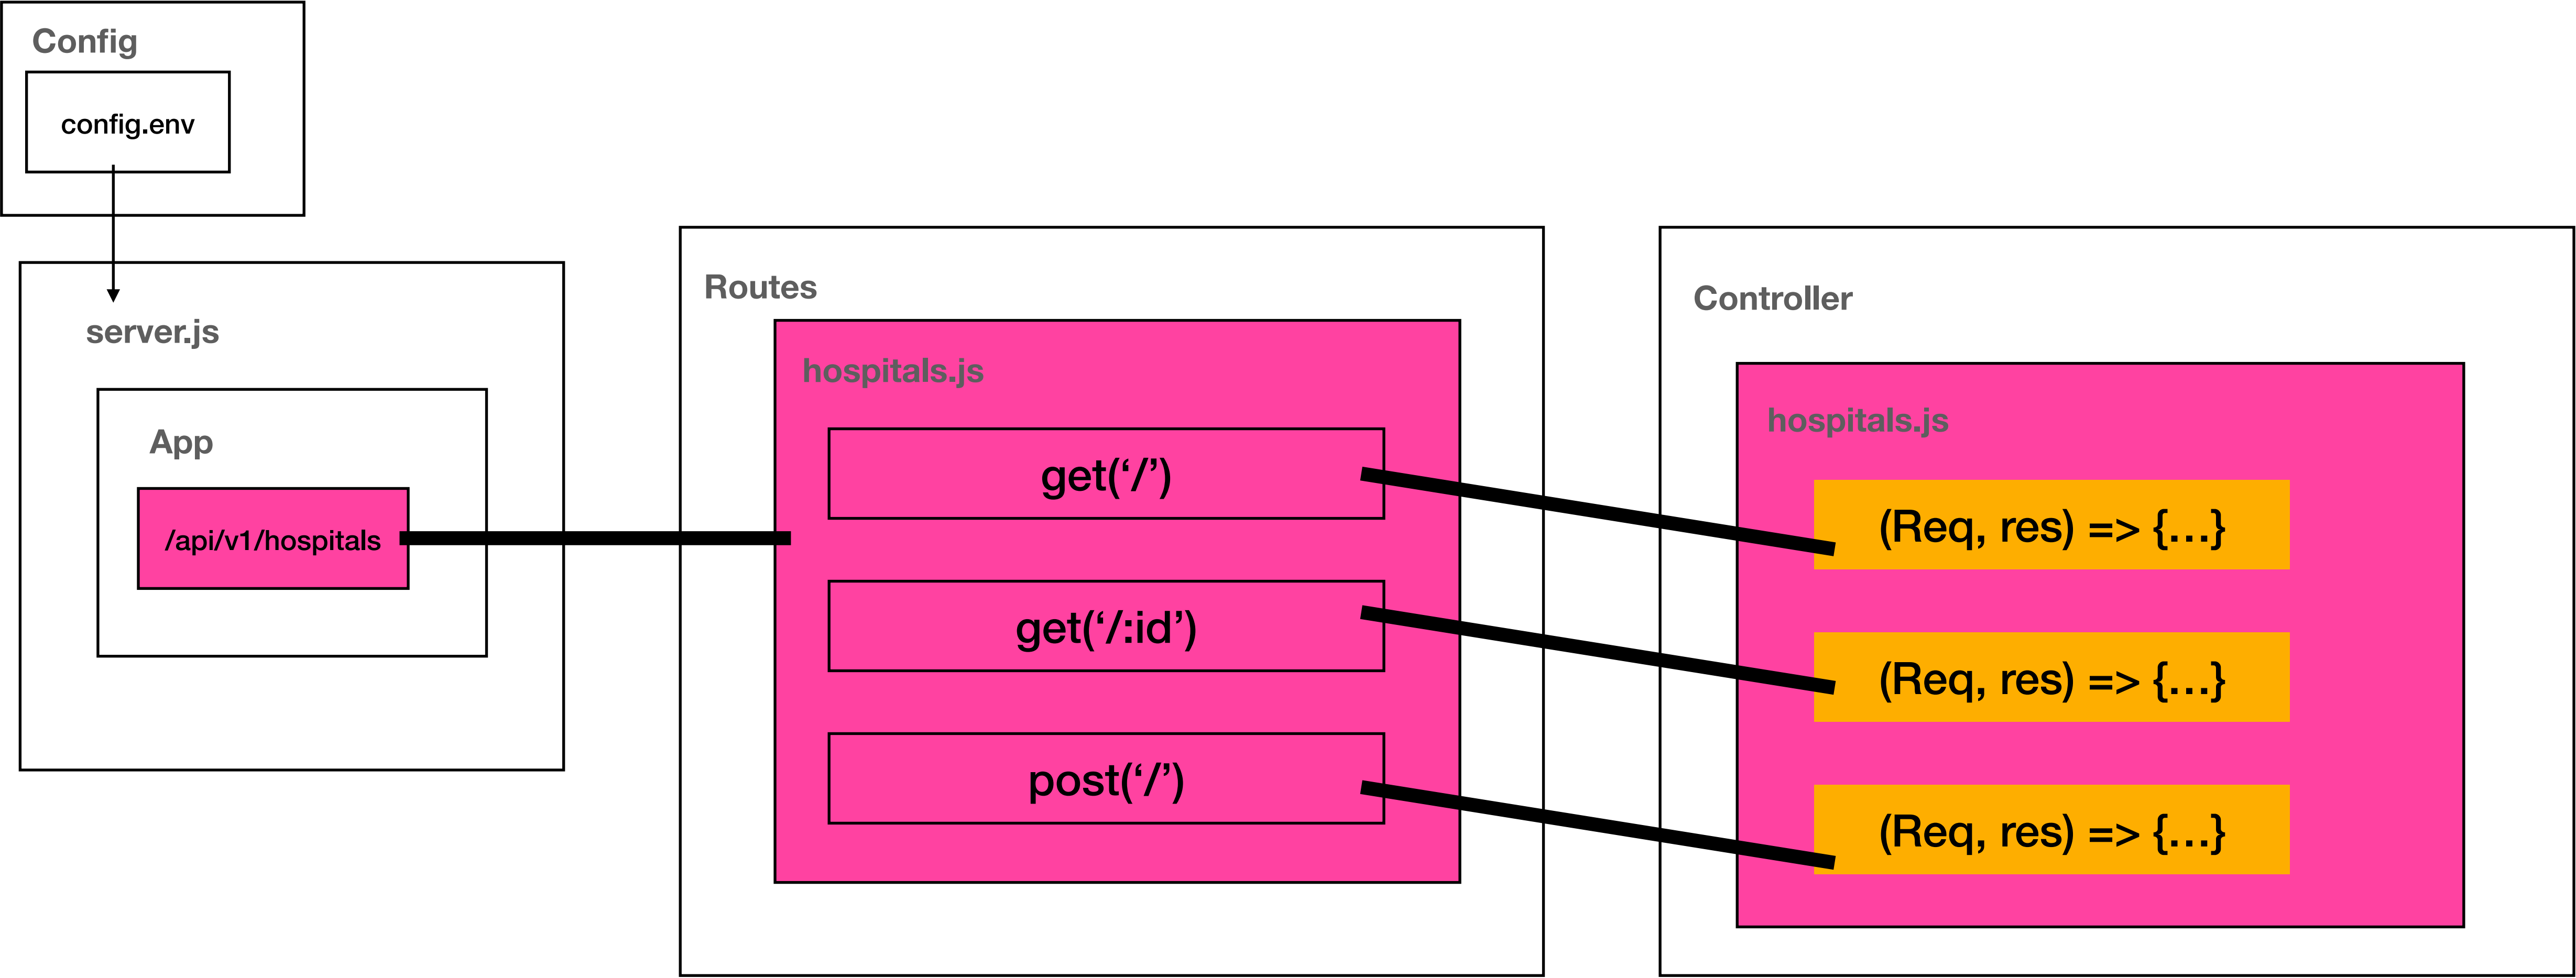

It began with 1 server file that has everything. A working server.

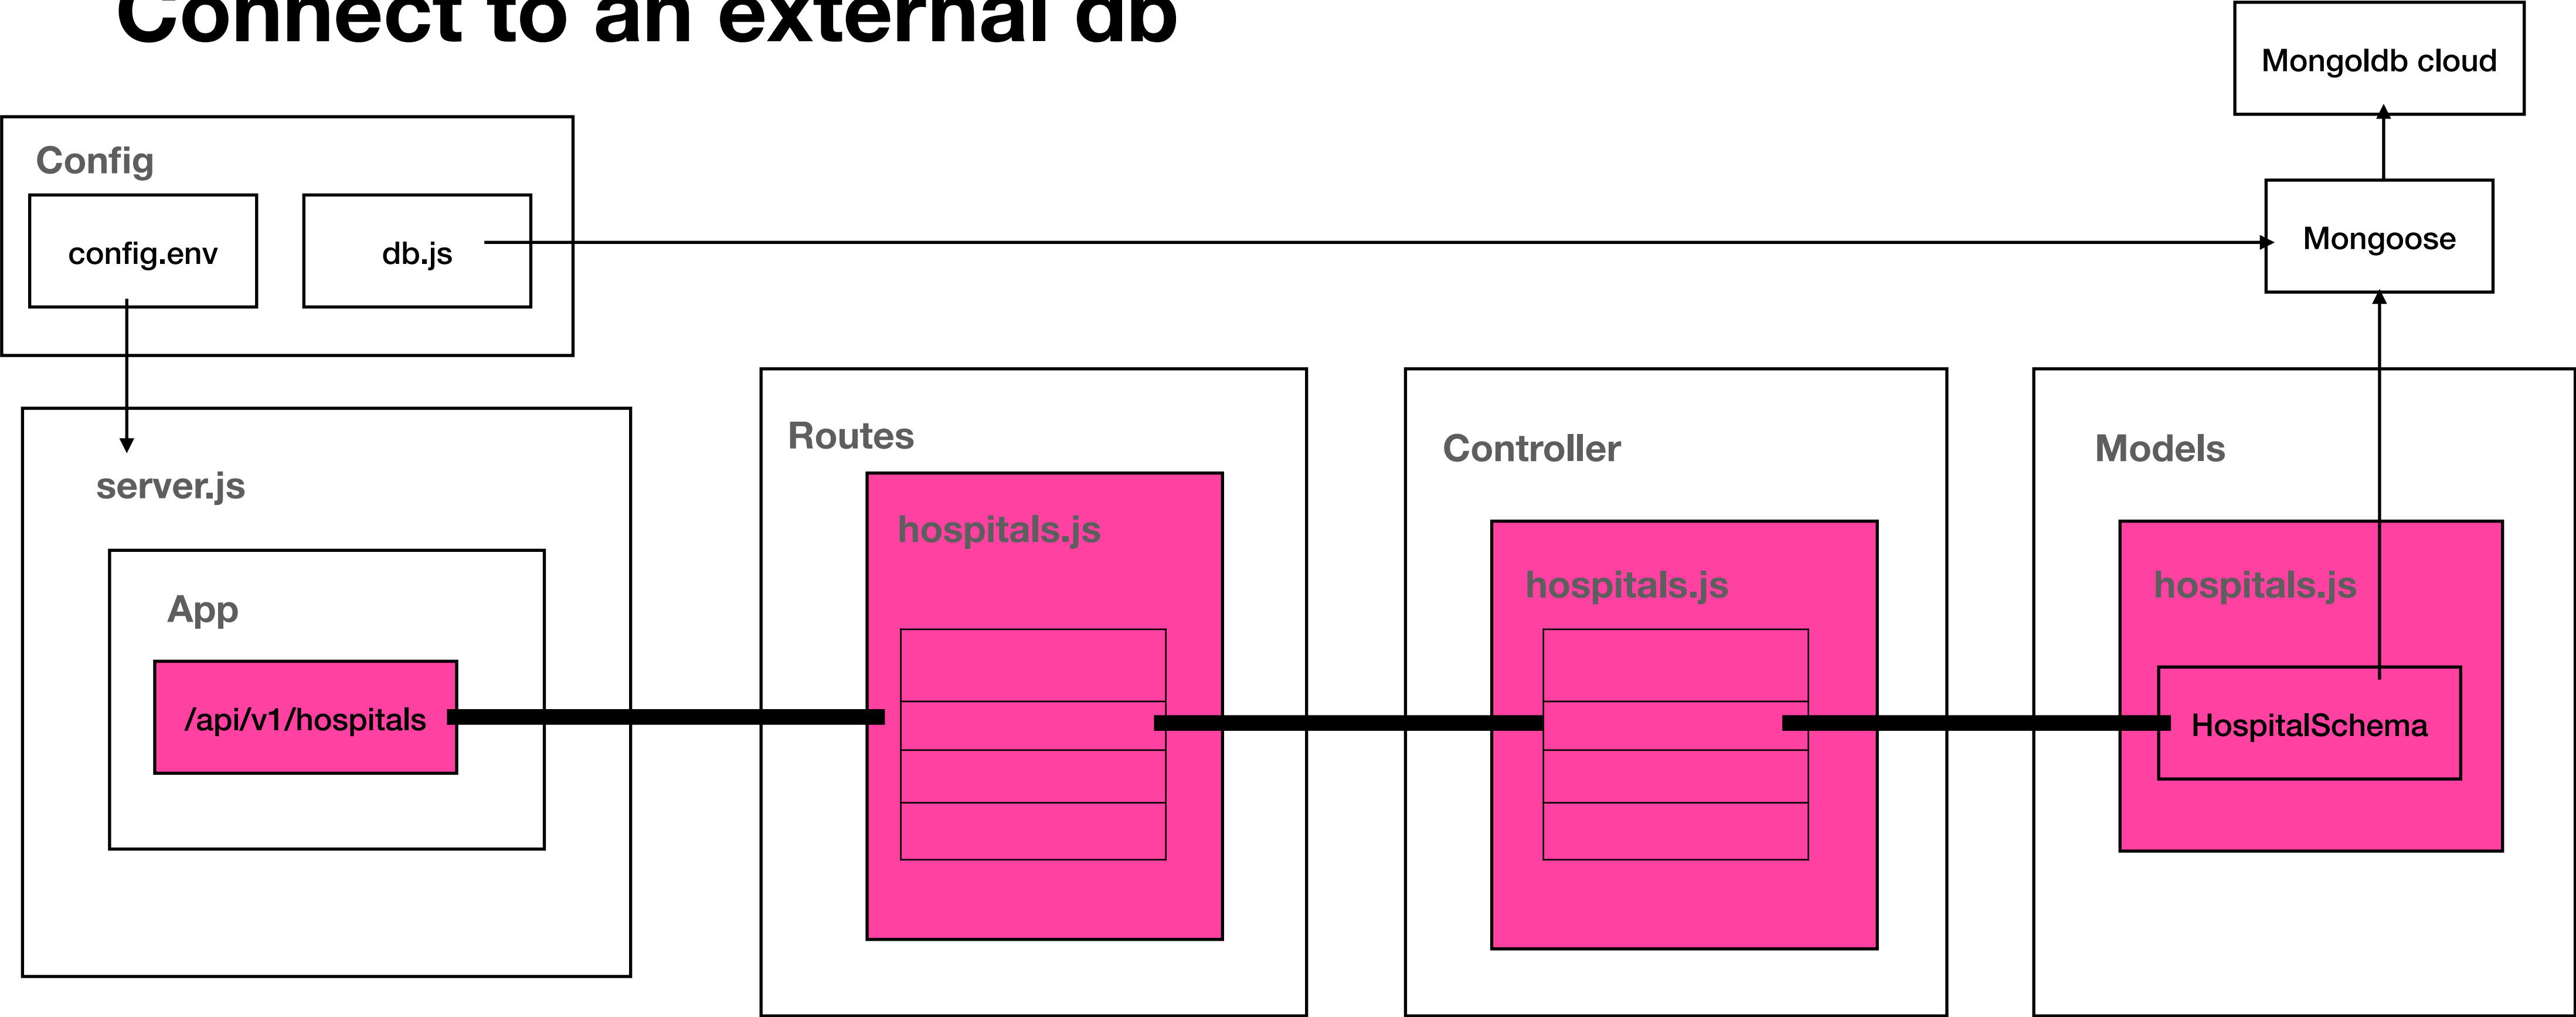

Router files to handle the routes with same prefix

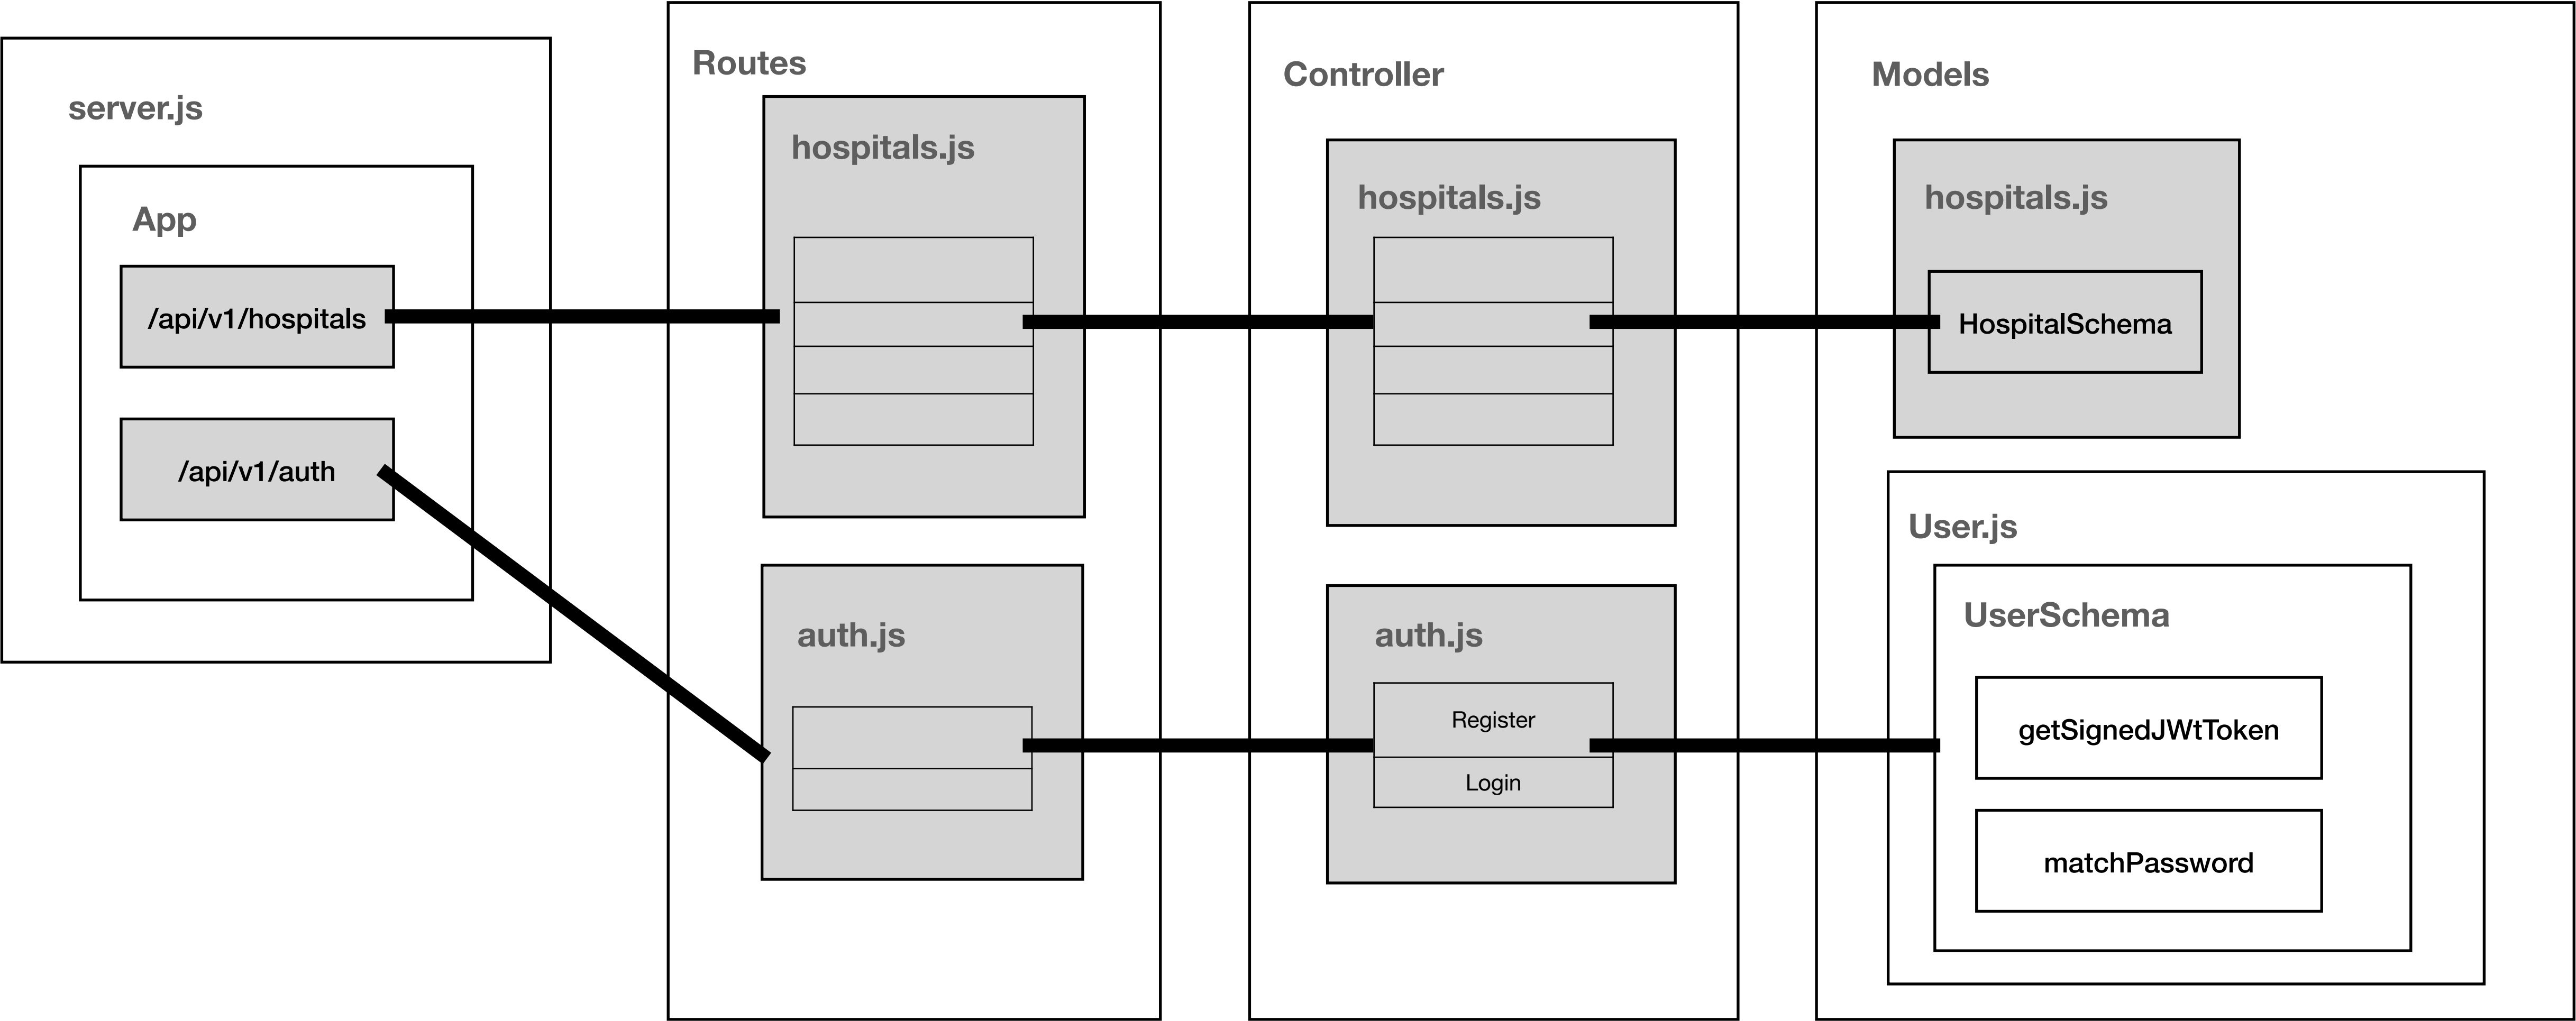

Extract the HTTP method handlers into a controller

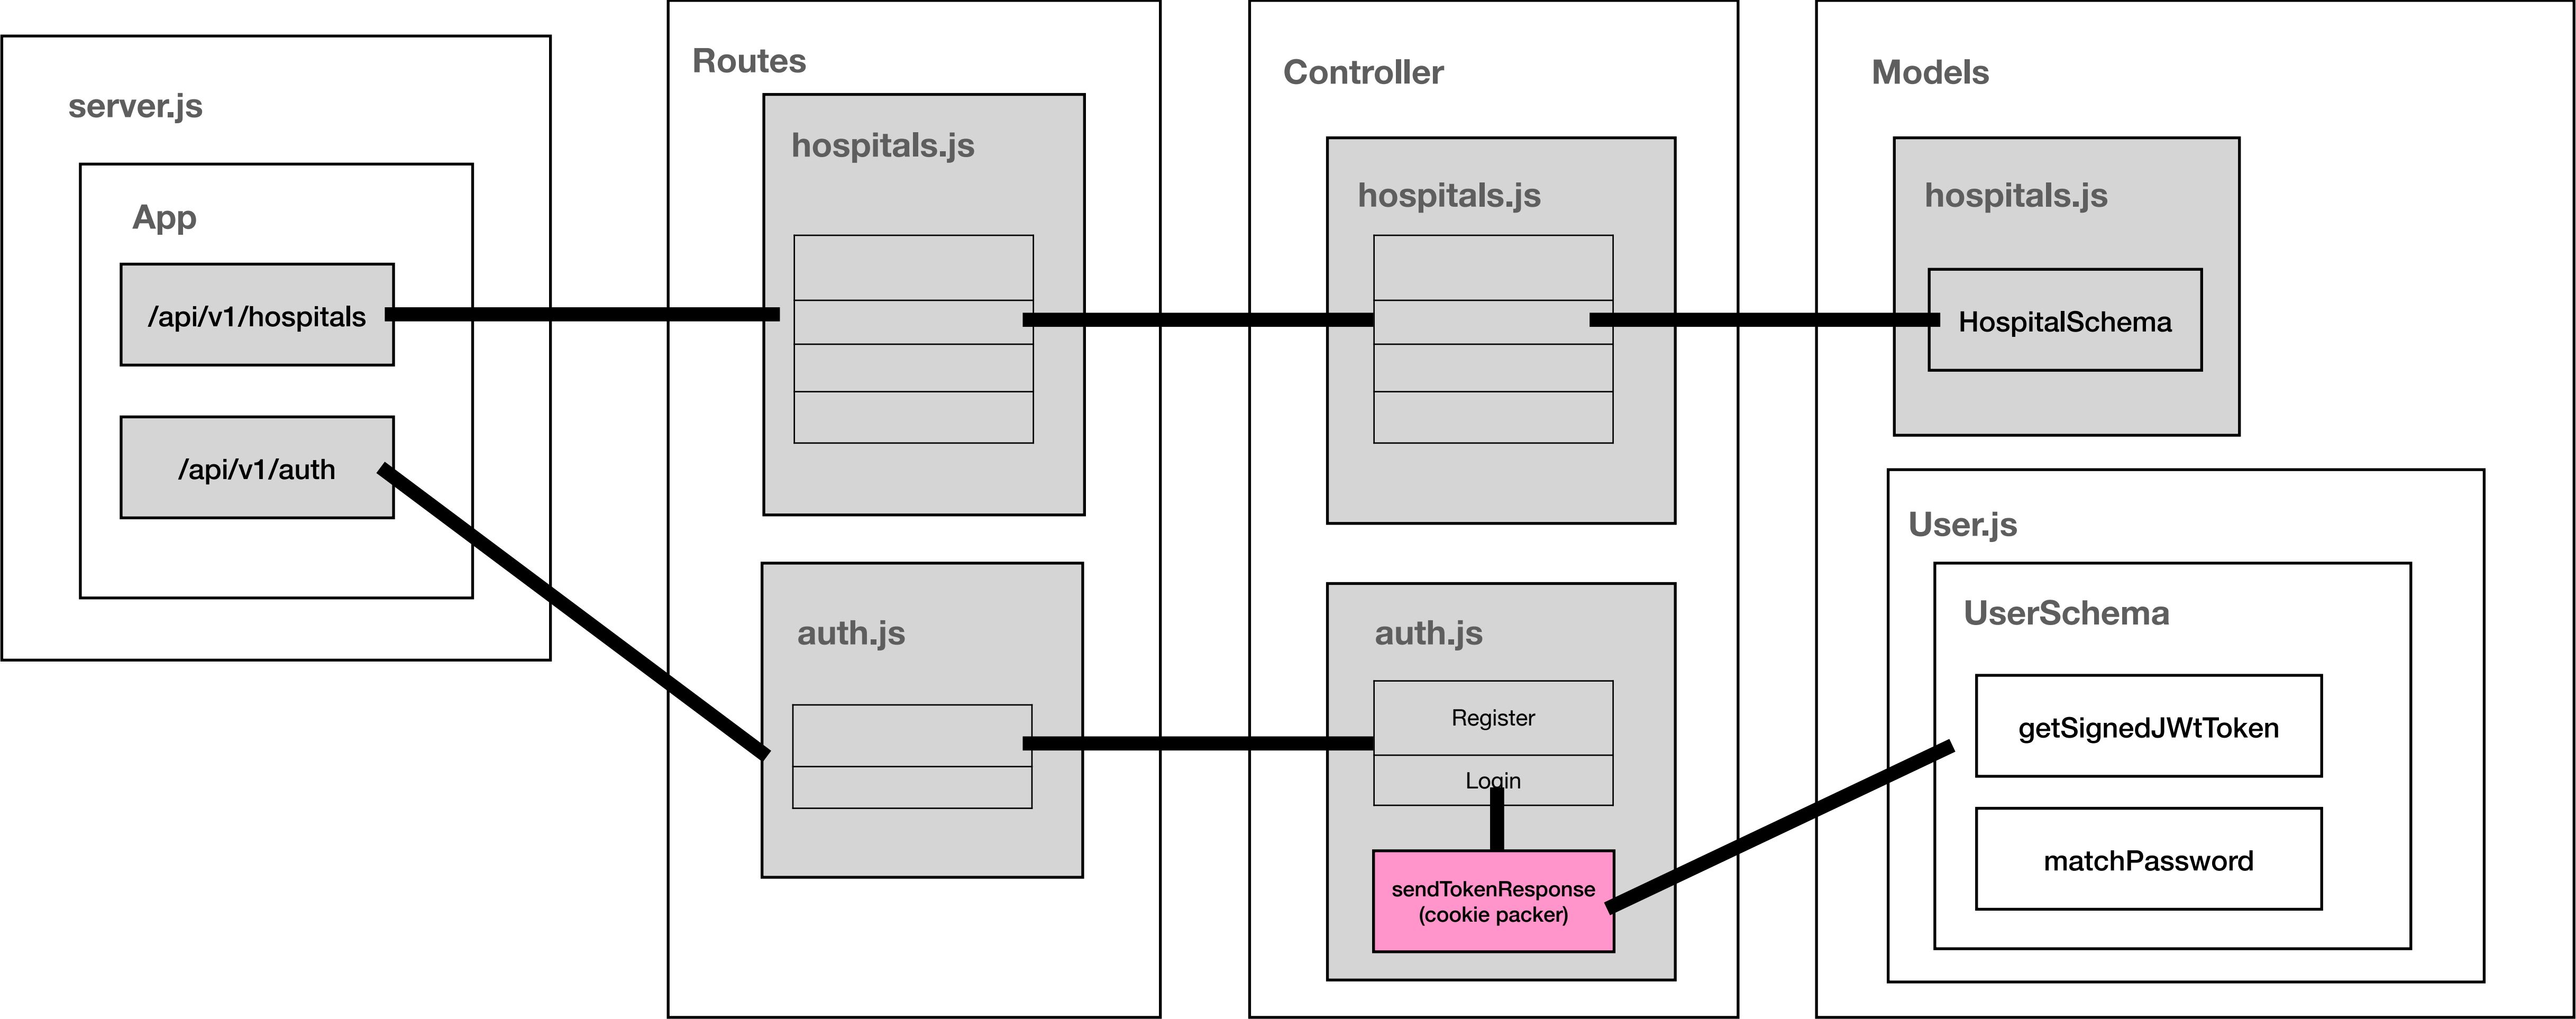

Connect to an external db

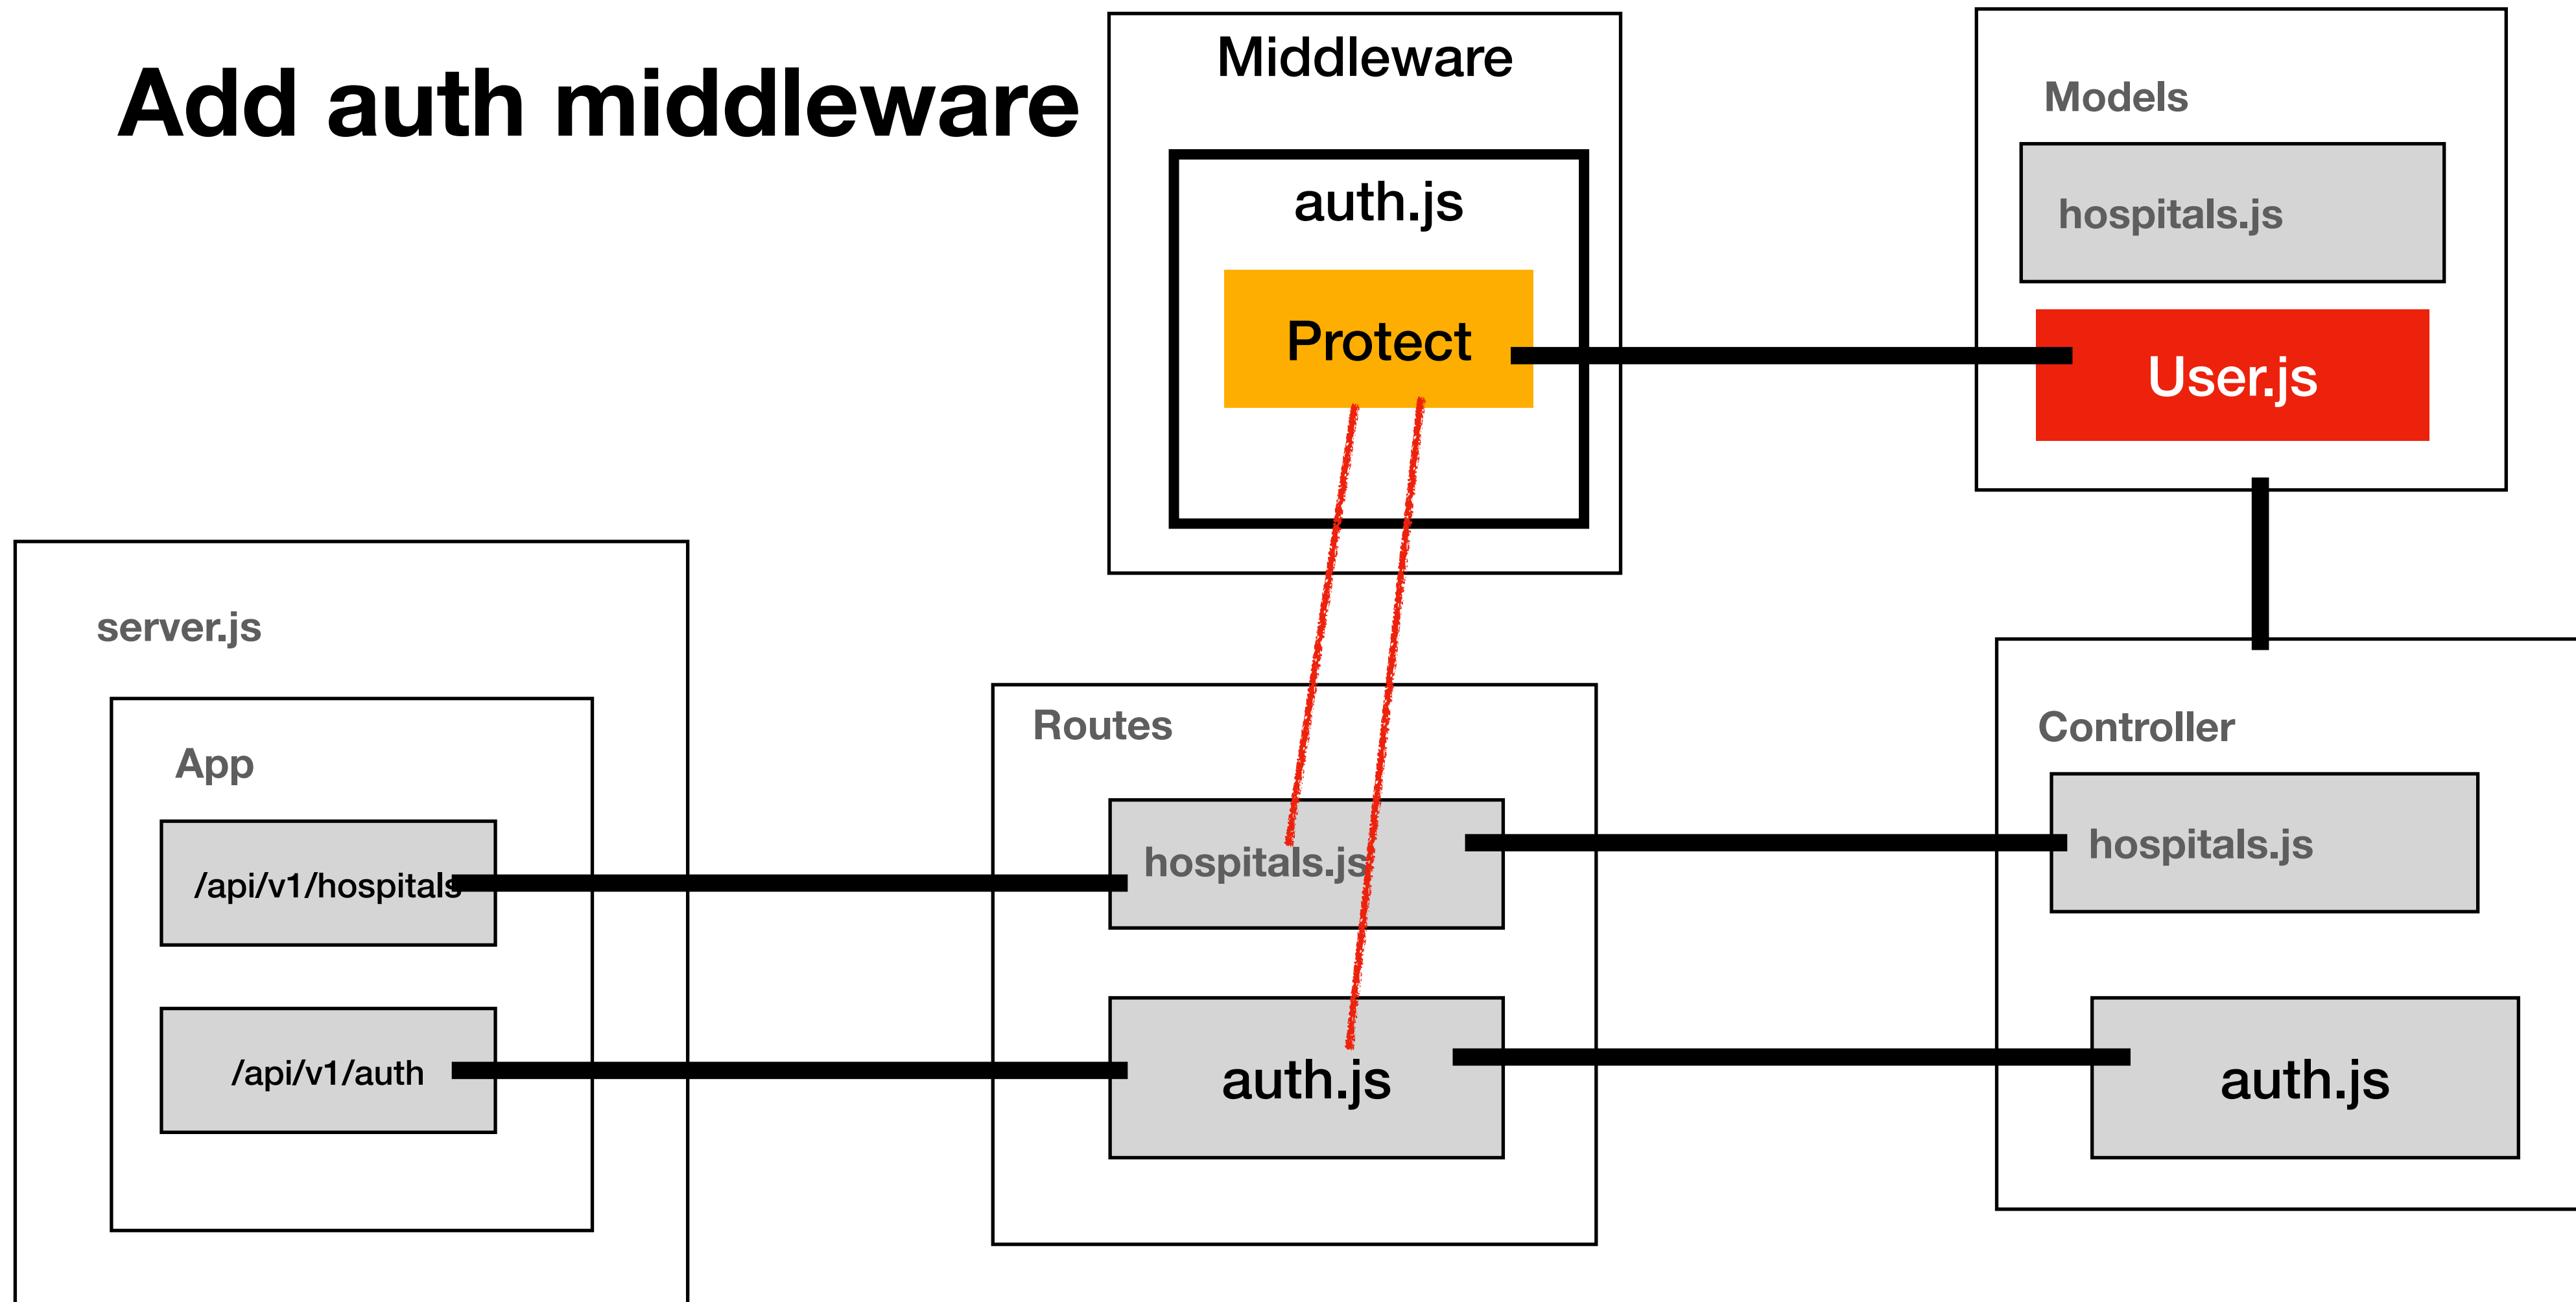

Add authentication Routes

Pack JWT Tokens into cookie

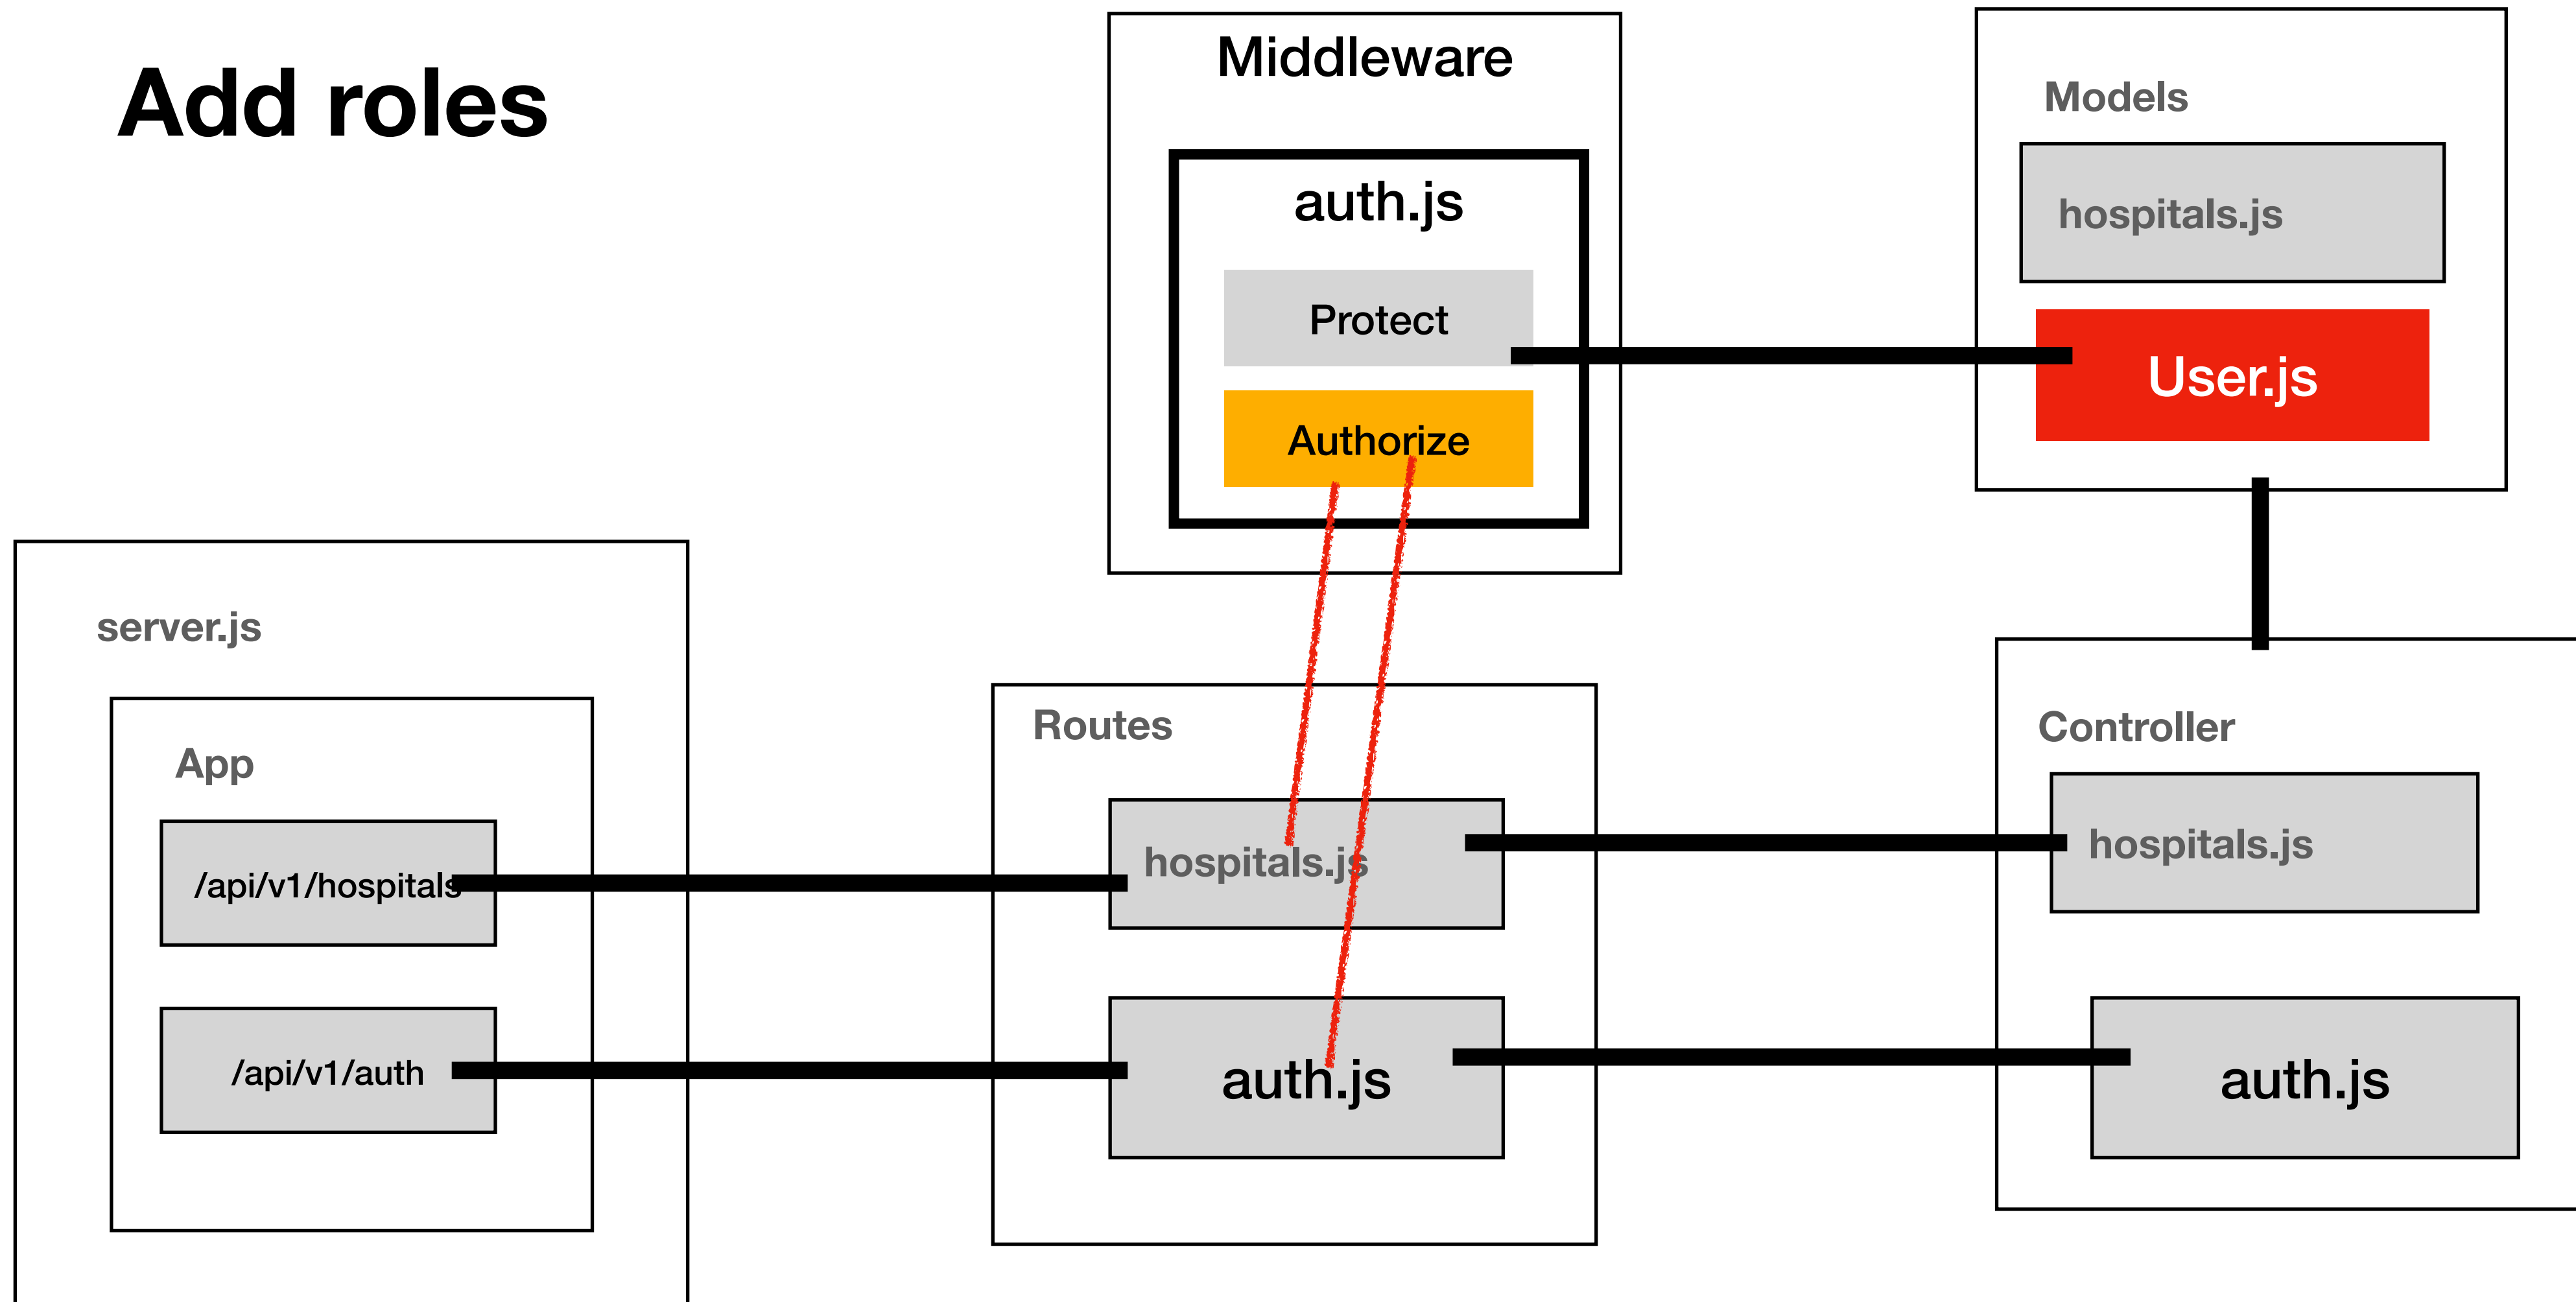

Add auth middleware

Note: Protect is just another HTTP method handler in the form `(req, res) => {... next()}`

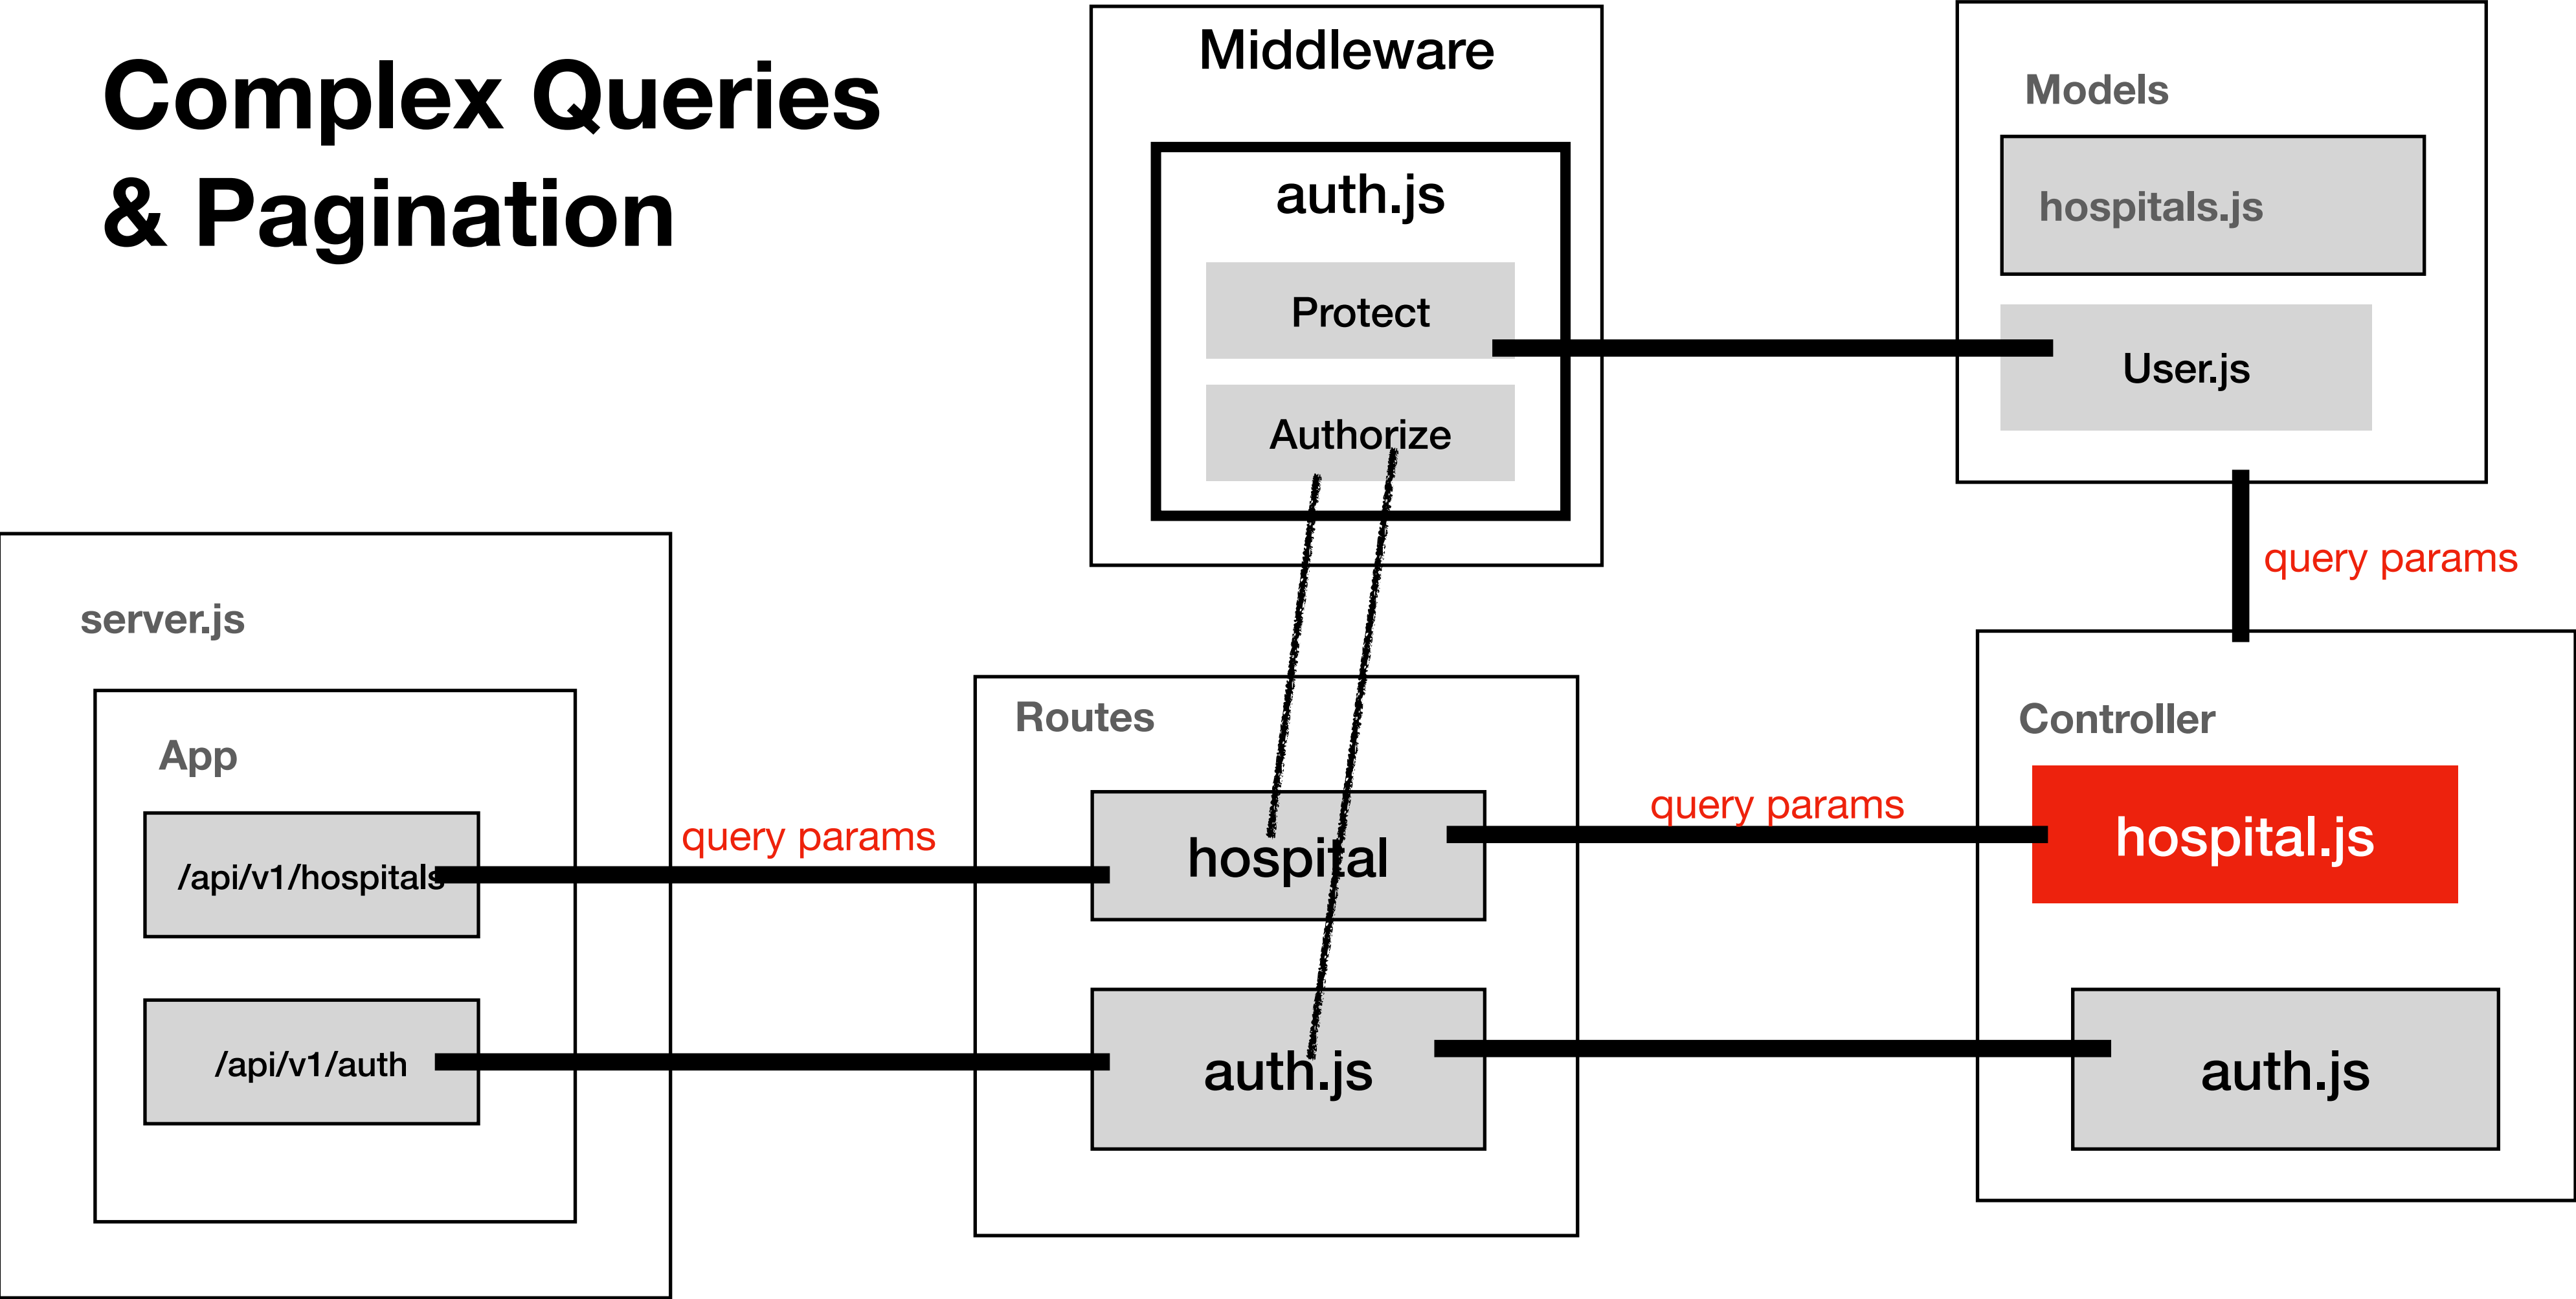

Add roles

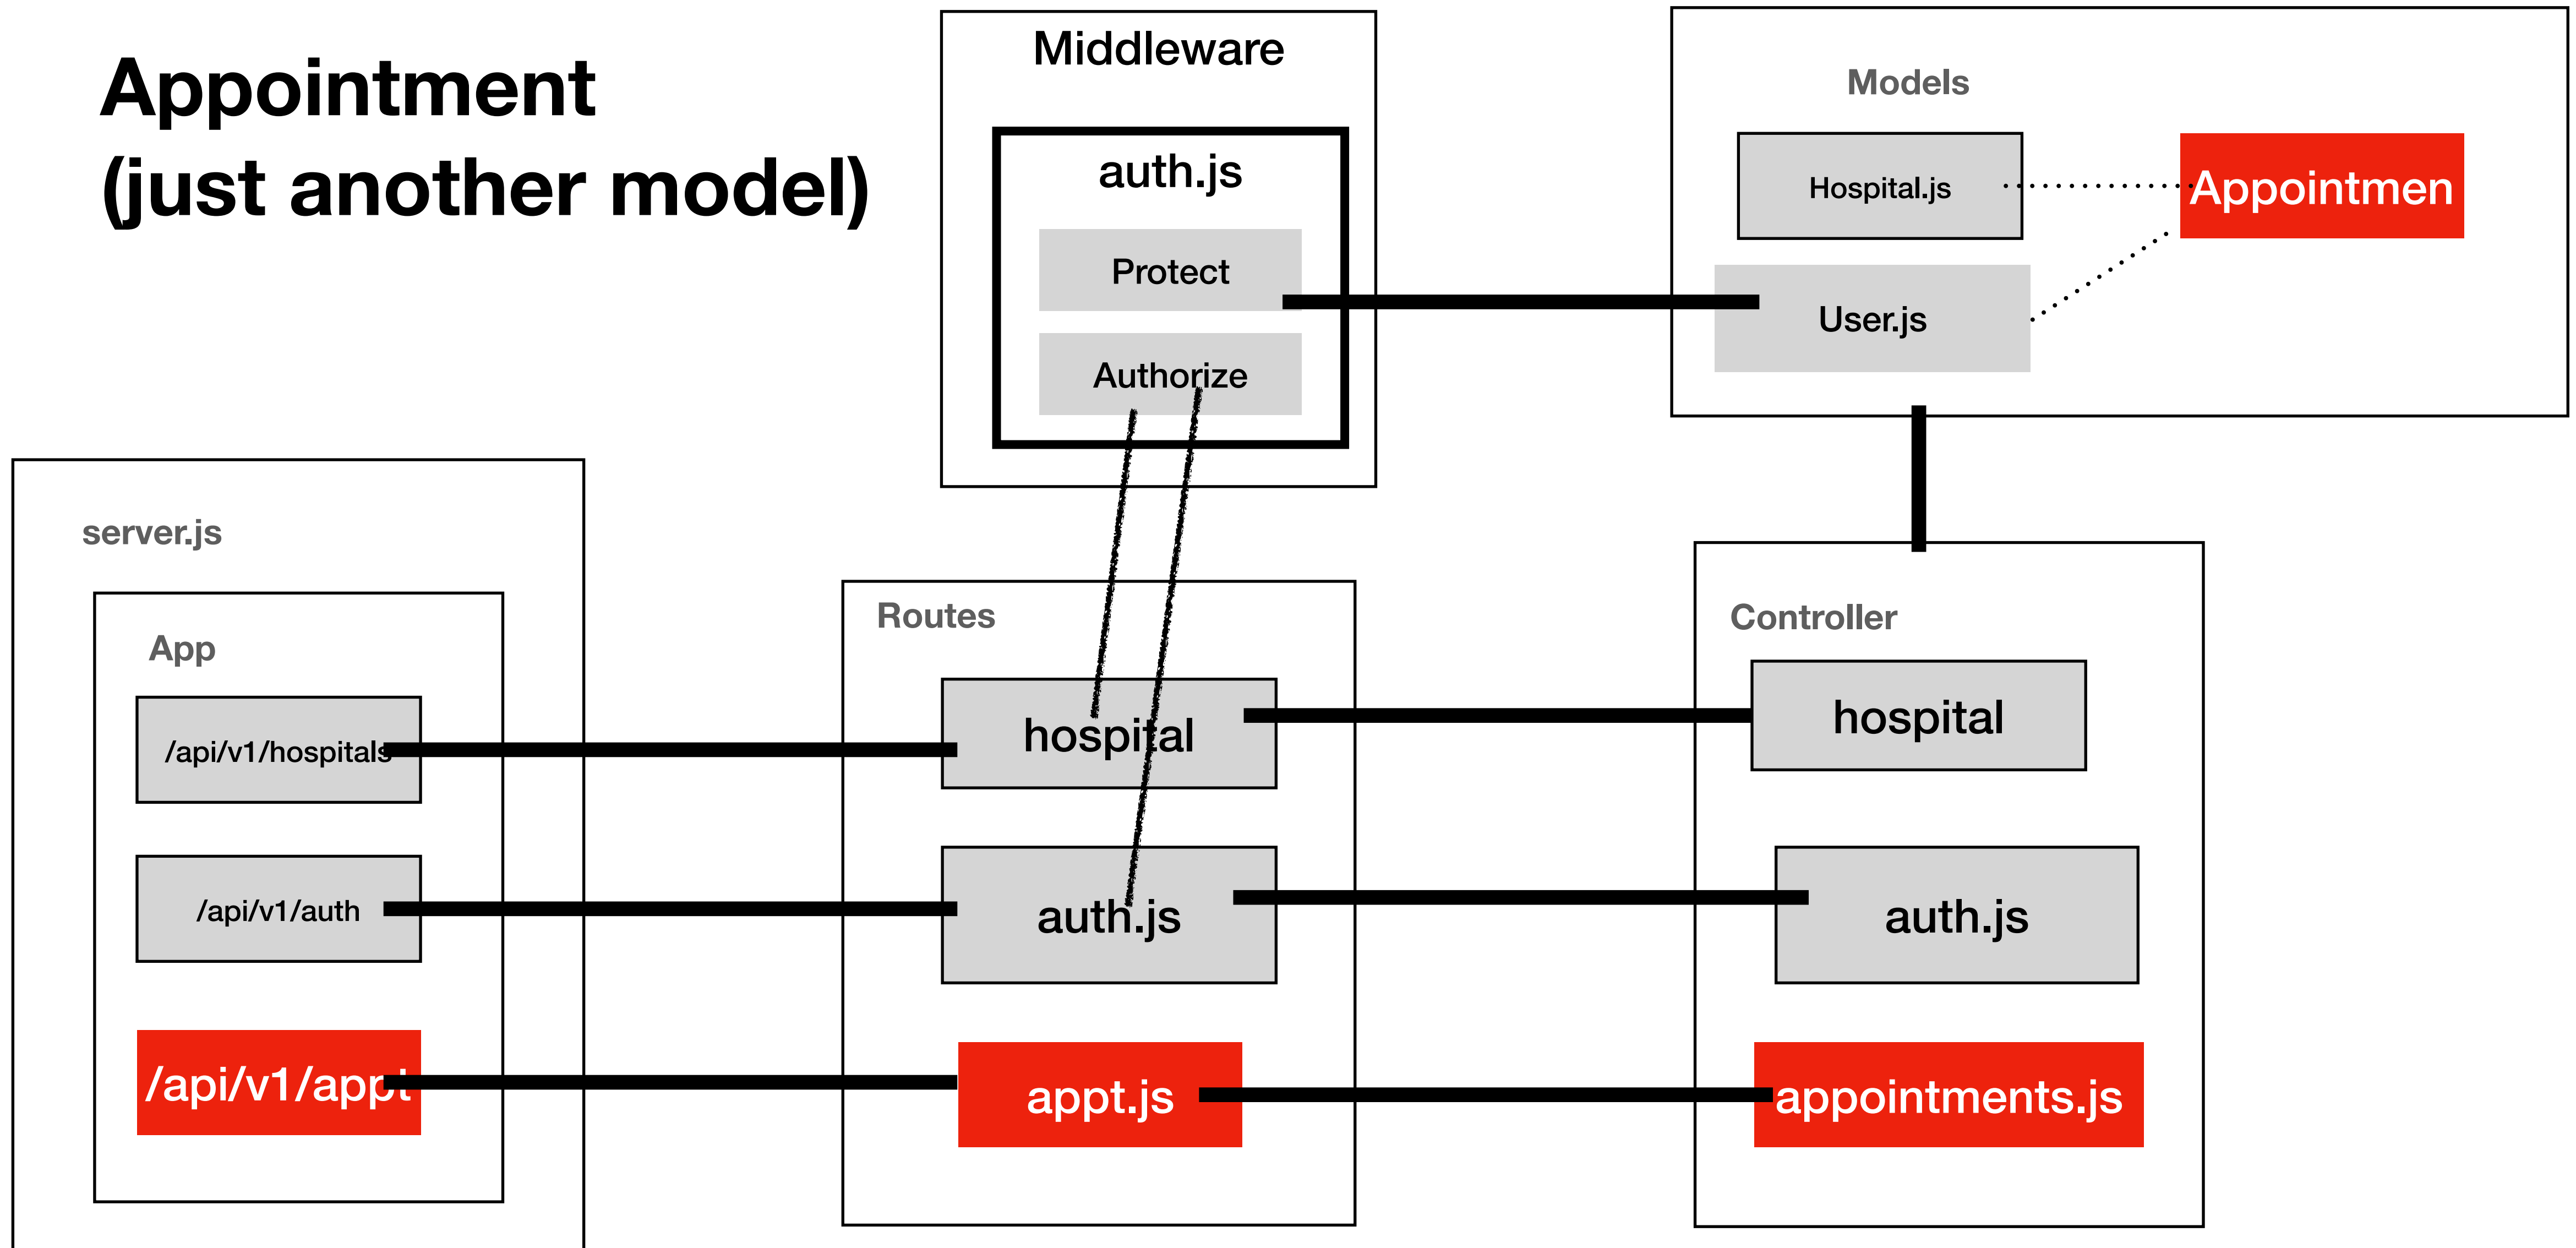

Note: 1) Unlike normal handler function, `Authorize` is a factory pattern function that returns a handler function `(req, res, next) => {...}` that depends on the roles,

2) So it will be used like `authorize(["admin", "user"])`, while `protect` could be used as `protect`

Complex Queries & Pagination

Appointment (just another model)

Add VacCenter -SQL (dockerized server)
